**Warnings**

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.  
Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

### Standalone Power Factor Correction (PFC) Controller in Continuous Conduction Mode (CCM)

#### Product Highlights

- High efficiency over the whole load range
- Lowest count of external components
- Accurate and adjustable switching frequency
- Integrated digital voltage loop compensation
- Fast output dynamic response during load jump
- External synchronization
- Low peak current limitation

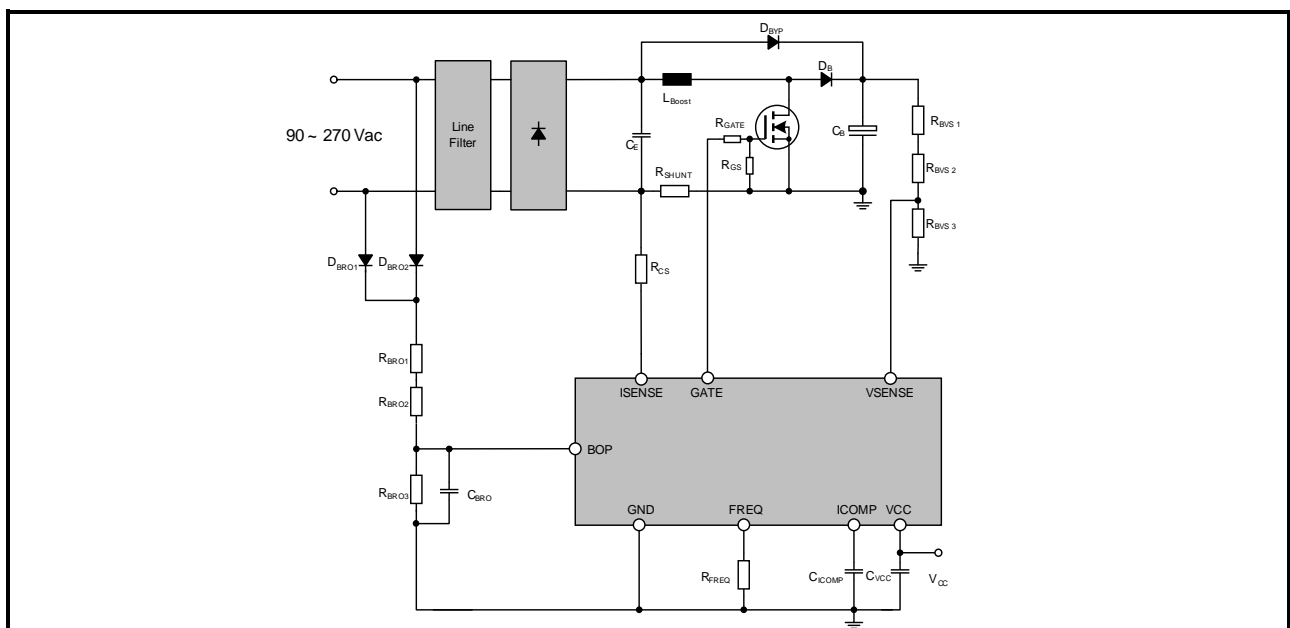

#### Features

- Continuous current operation mode PFC
- Wide input range of  $V_{cc}$  up to 25V
- Enhanced dynamic response without input current distortion
- Accurate brown-out protection threshold
- External current loop compensation for greater user flexibility
- Open loop protection
- Maximum duty cycle of 95% (typical)

#### Description

The ICE3PCS03G is a 8-pins wide input range controller IC for active power factor correction converters. It is designed for converters in boost topology, and requires few external components. Its power supply is recommended to be provided by an external auxiliary supply which will switch on and off the IC.

# 1 Pin Configuration and Functionality

## 1.1 Pin Configuration

Pin	Symbol	Function
1	ISENSE	Current Sense Input
2	GND	IC Ground
3	ICOMP	Current Loop Compensation
4	FREQ	Switching Frequency Setting
5	BOP	Brownout Protection
6	VSENSE	Bulk Voltage Sense
7	VCC	IC Supply Voltage
8	GATE	Gate Drive

Figure 1 Pin Configuration (top view)

## 1.2 Pin Functionality

### ISENSE (Current Sense Input)

The ISENSE Pin senses the voltage drop at the external sense resistor ( $R_{SHUNT}$ ). This is the input signal for the average current regulation in the current loop. It is also fed to the peak current limitation block.

During power up time, high inrush currents cause high negative voltage drop at  $R_{SHUNT}$ , driving currents out of pin 1 which could be beyond the absolute maximum

ratings. Therefore a series resistor ( $R_{CS}$ ) of around  $50\Omega$  is recommended in order to limit this current into the IC

### GND (IC Ground)

The ground potential of the IC.

### ICOMP (Current Loop Compensation)

Low pass filter and compensation of the current control loop. The capacitor which is connected at this pin integrates the output current of OTA6 and averages the current sense signal.

### FREQ (Frequency Setting)

This pin allows the setting of the operating switching frequency by connecting a resistor to ground. The frequency range is from 21kHz to 250kHz.

### BOP (Brownout Protection)

BOP monitors the AC input voltage for Brownout Protection.

### VSENSE

VSENSE is connected via a resistive divider to the bulk voltage. The voltage of VSENSE relative to GND represents the output voltage. The bulk voltage is monitored for voltage regulation, over voltage protection and open loop protection.

### VCC

VCC provides the power supply of the ground related to IC section.

### GATE

GATE is the output for driving the PFC MOSFET. Its gate drive voltage is clamped at 15V (typically).

## 2 Block Diagram

A functional block diagram is given in Figure 2. Note that the figure only shows the brief functional block and does not represent the implementation of the IC.

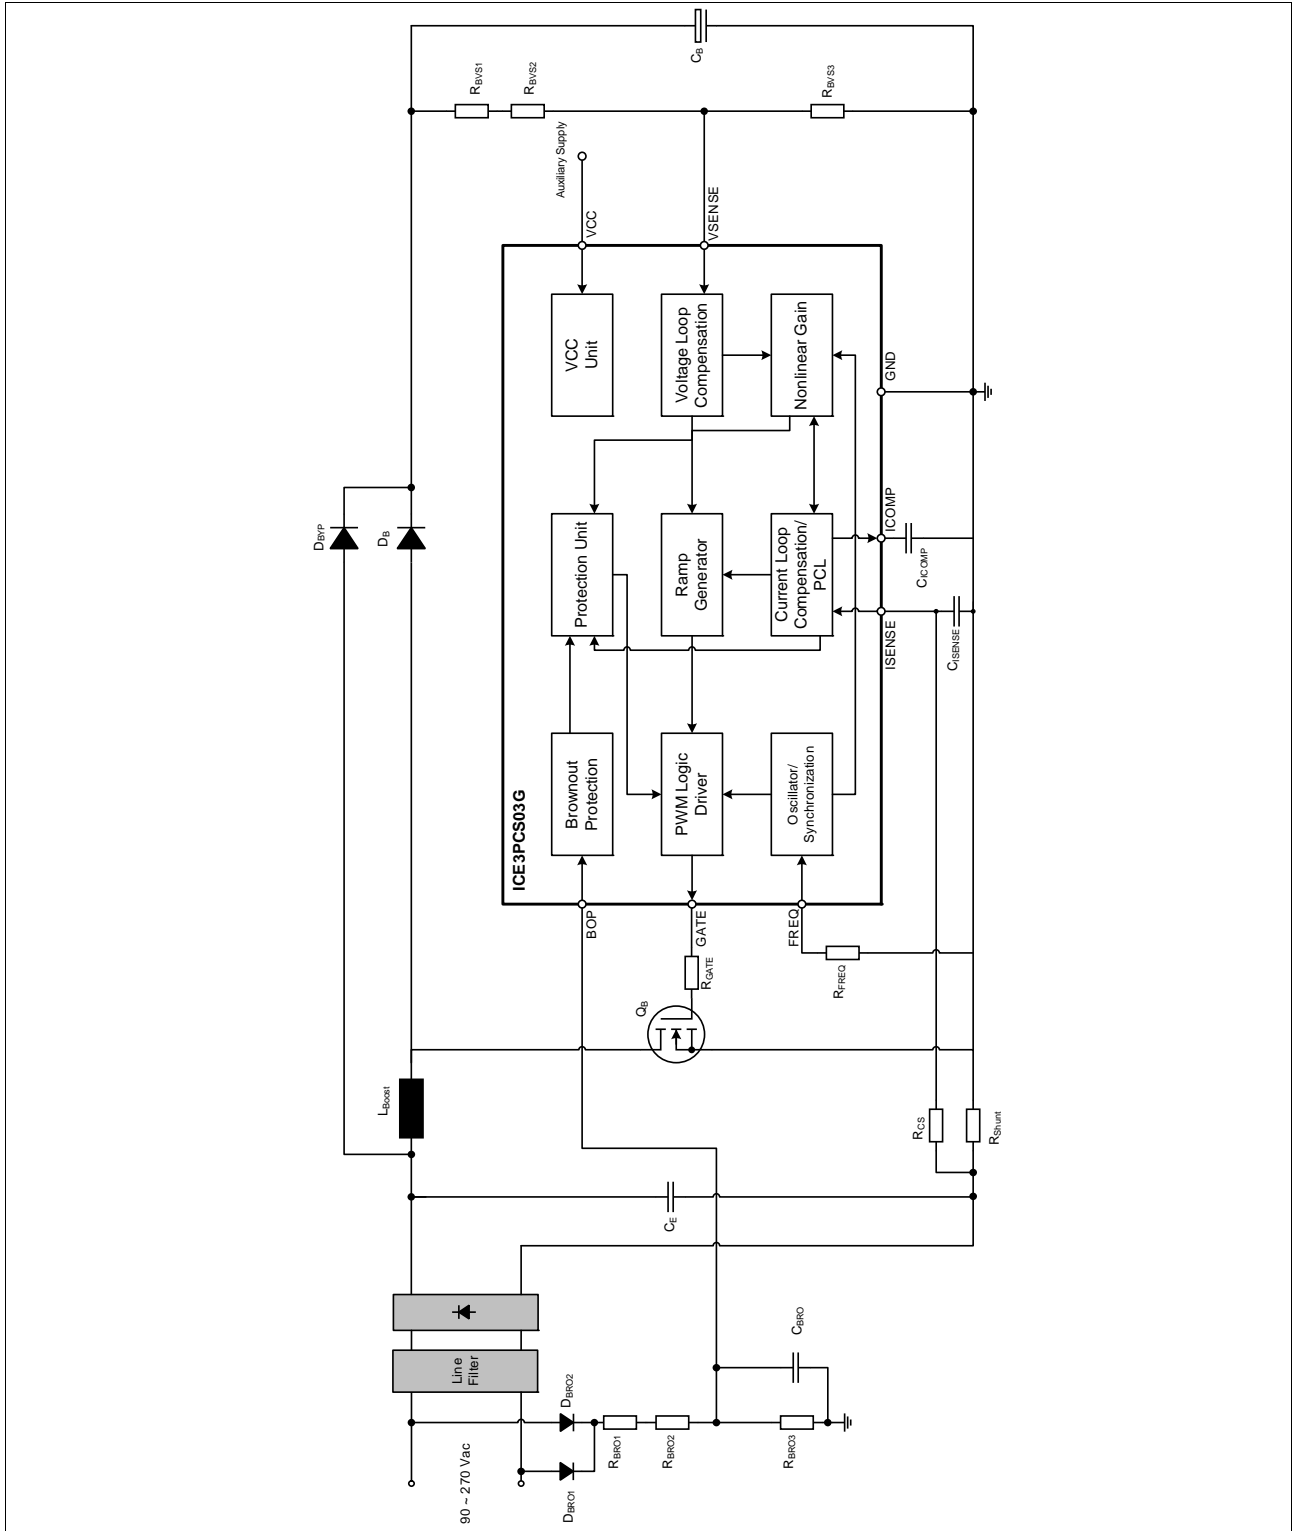

Figure 2 Block Diagram

**Table 1 Bill of Material**

Component	Parameters
Rectifier Bridge	GBU8J
$C_E$	100nF/X2/275V
$L_{Boost}$	750uH
$Q_B$	IPP60R199CP
$D_{BYP}$	MUR360
$D_B$	IDT04S60C
$C_B$	220 $\mu$ F/450V

$R_{BRO1...2}$	3.9M $\Omega$
$R_{BRO3}$	130k $\Omega$
$C_{BRO}$	3 $\mu$ F
$R_{shunt}$	60m $\Omega$
$C_{isense}$	1nF
$R_{CS}$	50 $\Omega$
$R_{GATE}$	3.3 $\Omega$
$R_{FREQ}$	67k $\Omega$
$C_{ICOMP}$	4.7nF/25V
$R_{BVS1...2}$	1.5M $\Omega$
$R_{BVS3}$	18.85k $\Omega$

## 3 Functional Description

### 3.1 General

The ICE3PCS03G is a 8-pins control IC for power factor correction converters. It is suitable for wide range line input applications from 85 to 265 VAC with overall efficiency above 90%. The IC supports converters in boost topology and it operates in continuous conduction mode (CCM) with average current control. The IC operates with a cascaded control; the inner current loop and the outer voltage loop. The inner current loop of the IC controls the sinusoidal profile for the average input current. It uses the dependency of the PWM duty cycle on the line input voltage to determine the corresponding input current. This means the average input current follows the input voltage as long as the device operates in CCM. Under light load condition, depending on the choke inductance, the system may enter into discontinuous conduction mode (DCM) resulting in a higher harmonics but still meeting the Class D requirement of IEC 1000-3-2.

The outer voltage loop controls the output bulk voltage, integrated digitally within the IC. Depending on the load condition, internal PI compensation output is converted to an appropriate DC voltage which controls the amplitude of the average input current.

The IC is equipped with various protection features to ensure safe operating condition for both the system and device.

### 3.2 Power Supply

An internal under voltage lockout (UVLO) block monitors the VCC power supply. As soon as it exceeds 12.0V and both voltages at pin 6 (VSENSE) >0.5V and pin 5 (BOP) >1.25V, the IC begins operating its gate drive and performs its startup as shown in Figure 3.

If VCC drops below 11V, the IC is off. The IC will then be consuming typically 1.4mA, whereas consuming 6.4mA during normal operation

The IC can be turned off and forced into standby mode by pulling down the voltage at pin 6 (VSENSE) below 0.5V.

Figure 3 State of Operation respect to VCC

### 3.3 Start-up

During power up when the  $V_{out}$  is less than 95% of the rated level, internal voltage loop output increases from initial voltage under the soft-start control. This results in a controlled linear increase of the input current from 0A thus reducing the stress in the external components.

Once  $V_{out}$  has reached 95% of the rated level, the soft-start control is released to achieve good regulation and dynamic response.

### 3.4 Frequency Setting and External Synchronization

The IC can provide external switching frequency setting by an external resistor  $R_{FREQ}$  and the online synchronization by external pulse signal at FREQ pin.

#### 3.4.1 Frequency Setting

The switching frequency of the PFC converter can be set with an external resistor  $R_{FREQ}$  at FREQ pin as shown Figure 2. The pin voltage at  $V_{FREQ}$  is typical 1V. The corresponding capacitor for the oscillator is integrated in the device and the  $R_{FREQ}/\text{frequency}$  is given in Figure 4. The recommended operating frequency range is from 21kHz to 250kHz. As an example, a  $R_{FREQ}$  of 67k $\Omega$  at pin FREQ will set a switching frequency  $F_{SW}$  of 65kHz typically.

## Functional Description

Figure 4 Frequency Versus  $R_{FREQ}$

### 3.4.2 External Synchronization

The switching frequency can be synchronized to the external pulse signal after 6 external pulses delay once the voltage at the FREQ pin is higher than 2.5V. The synchronization means two points. Firstly, the PFC switching frequency is tracking the external pulse signal frequency. Secondly, the falling edge of the PFC signal is triggered by the rising edge of the external pulse signal. Figure 5 shows the blocks of frequency setting and synchronization. The external  $R_{SYN}$  combined with  $R_{FREQ}$  and the external diode  $D_{SYN}$  can ensure pin voltage to be kept between 1.0V (clamped externally) and 5V (maximum pin voltage). If the external pulse signal has disappeared longer than 108 $\mu$ s (typical) the switching frequency will be synchronized to internal clock set by the external resistor  $R_{FREQ}$ .

Figure 5 Frequency Setting and Synchronization

### 3.5 Voltage Loop

The voltage loop is the outer loop of the cascaded control scheme which controls the PFC output bus voltage  $V_{OUT}$ . This loop is closed by the feedback sensing voltage at  $V_{SENSE}$  which is a resistive divider tapping from  $V_{OUT}$ . The pin  $V_{SENSE}$  is the input of sigma-delta ADC which has an internal reference of 2.5V and sampling rate of 3.55kHz (typical). The voltage loop compensation is integrated digitally for better dynamic response and saving design effort. Figure 6 shows the important blocks of this voltage loop.

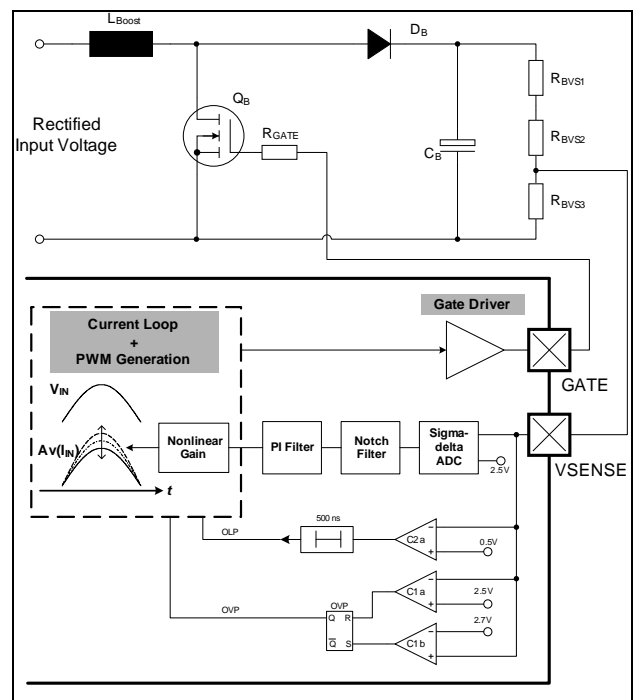

Figure 6 Voltage Loop

#### 3.5.1 Notch Filter

In the PFC converter, an averaged current through the output diode of rectified sine waveform charges the output capacitor and results in a ripple voltage at the output capacitor with a frequency two times of the line frequency. In this digital PFC, a notch filter is used to remove the ripple of the sensed output voltage while keeping the rest of the signal almost uninfluenced. In this way, an accurate and fast output voltage regulation without influence of the output voltage ripple is achieved.

#### 3.5.2 Voltage Loop Compensation

The Proportion-Integration (PI) compensation of the voltage loop is integrated digitally inside the IC. The digital data out of the PI compensator is converted to analog voltage for current loop control.

## Functional Description

The nonlinear gain block controls the amplitude of the regulated inductor current. The input of this block is the output voltage of integrated PI compensator. This block has been designed to reduce the voltage loop dependency on the input voltage in order to support the wide input voltage range (85VAC-265VAC). Figure 7 gives the relative output power transfer curve versus the digital word from the integrated PI compensator. The output power at the input voltage of 85VAC and maximum digital word of 256 from PI compensator is set as the normative power and the power curves at different input voltage present the relative power to the normative one.

Figure 7 Power Transfer Curve

### 3.6 Average Current Control

The choke current is sensed through the voltage across the shunt resistor and averaged by the ICOMP pin capacitor so that the IC can control the choke current to track the instant variation of the input voltage.

#### 3.6.1 Complete Current Loop

The complete system current loop is shown in Figure 8. It consists of the current loop block which averages the voltage at ISENSE pin resulted from the inductor current flowing across  $R_{shunt}$ . The averaged waveform is compared with an internal ramp in the ramp generator and PWM block. Once the ramp crosses the average waveform, the comparator C10 turns on the driver stage through the PWM logic block. The Nonlinear Gain block defines the amplitude of the inductor current. The following sections describe the functionality of each individual blocks.

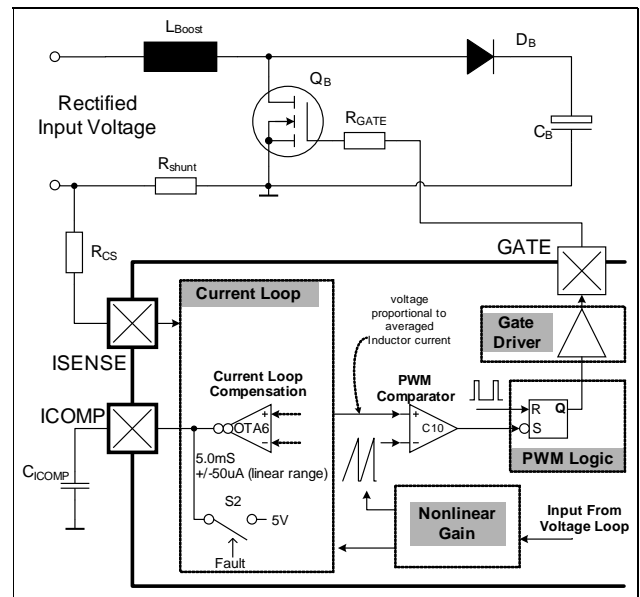

Figure 8 Complete System Current Loop

#### 3.6.2 Current Loop Compensation

The compensation of the current loop is implemented at the ICOMP pin. This is OTA6 output and a capacitor  $C_{ICOMP}$  has to be installed at this node to ground (see Figure 8). Under normal mode of the operation, this pin gives a voltage which is proportional to the averaged inductor current. This pin is internally shorted to 5V in the event of standby mode.

#### 3.6.3 Pulse Width Modulation (PWM)

The IC employs an average current control scheme in continuous mode (CCM) to achieve the power factor correction. Assuming the voltage loop is working and output voltage is kept constant, the off duty cycle  $D_{OFF}$  for a CCM PFC system is given as:

$$D_{OFF} = V_{IN} / V_{OUT}$$

From the above equation,  $D_{OFF}$  is proportional to  $V_{IN}$ .

The objective of the current loop is to regulate the average inductor current such that it is proportional to the off duty cycle  $D_{OFF}$ , and thus to the input voltage  $V_{IN}$ . Figure 9 shows the scheme to achieve the objective.

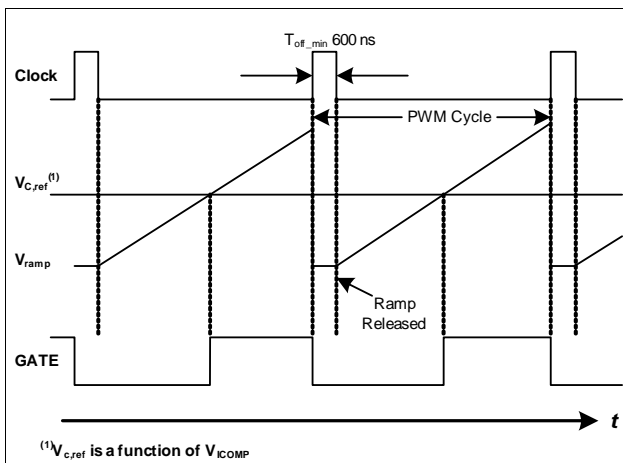

## Functional Description

**Figure 9 Average Current Control in CCM**

The PWM is performed by the intersection of a ramp signal with the averaged inductor current at pin 3 (ICOMP). The PWM cycles starts with the Gate turn off for a duration of  $T_{OFFMIN}$  (600ns typ.) and the ramp is kept discharged. The ramp is allowed to rise after the  $T_{OFFMIN}$  expires. The off time of the boost transistor ends at the intersection of the ramp signal and the averaged current waveform. This results in the proportional relationship between the average current and the off duty cycle  $D_{OFF}$ .

Figure 10 shows the timing diagrams of the  $T_{OFFMIN}$  and the gate waveforms.

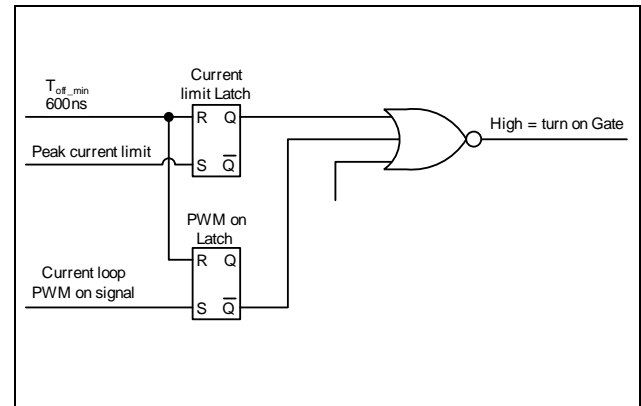

**Figure 10 Ramp and PWM waveforms**

### 3.7 PWM Logic

The PWM logic block prioritizes the control input signal and generates the final logic signal to turn on the driver stage. The speed of the logic gates in this block, together with the width of the reset pulse  $T_{OFFMIN}$ , are designed to meet a maximum duty cycle  $D_{MAX}$  of 95% at the GATE output under 65kHz of operation.

In case of high input currents which results in Peak Current Limitation, the GATE will be turned off

immediately and maintained in off state for the current PWM cycle. The signal  $T_{OFFMIN}$  resets (highest priority, overriding other input signals) both the current limit latch and the PWM on latch as illustrated in Figure 11.

**Figure 11 PWM LOGIC**

### 3.8 System Protection

The IC provides numerous protection features in order to ensure the PFC system in safe operation.

#### 3.8.1 Input Voltage Brownout Protection(BOP)

Brownout occurs when the input voltage  $V_{IN}$  falls below the minimum input voltage of the design (i.e. 85V for universal input voltage range) and the  $V_{CC}$  has not entered into the  $V_{CCUVLO}$  level yet. For a system without BOP, the boost converter will increasingly draw a higher current from the mains at a given output power which may exceed the maximum design values of the input current.

ICE3PCS03G provides a new BOP feature whereby it senses directly the input voltage for Input Brown-Out condition via an external resistor/capacitor/diode network shown in Figure 12. This network provides a filtered value of  $V_{IN}$  which turns the IC on when the voltage at pin 5 (BOP) is more than 1.25V. The IC enters into the fault mode when BOP goes below 1.0V. The hysteresis prevents the system to oscillate between normal and fault mode. Note also that the peak of  $V_{IN}$  needs to be at least 20% of the rated  $V_{OUT}$  in order to overcome OLP and powerup system.

## Functional Description

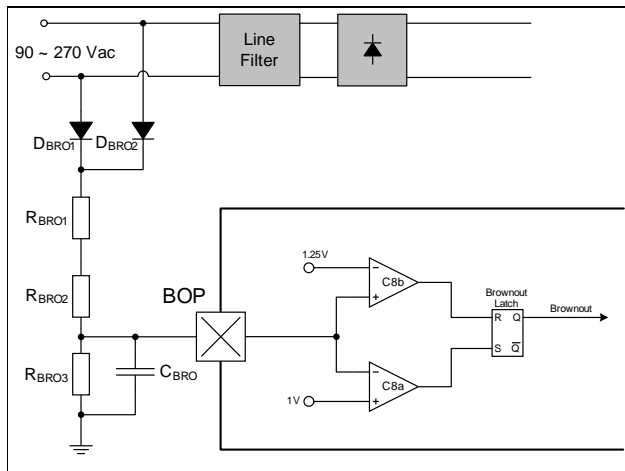

Figure 12 Input Brownout Protection

### 3.8.2 Peak Current Limit (PCL)

The IC provides a cycle by cycle peak current limitation (PCL). It is active when the voltage at pin 1 (ISENSE) reaches  $-0.4V$ . This voltage is amplified by a factor of  $-2.5$  and connected to comparator with a reference voltage of  $1.0V$  as shown in Figure 13. A deglitcher with  $200ns$  after the comparator improves noise immunity to the activation of this protection.

Figure 13 Peak Current Limit (PCL)

### 3.8.3 Open Loop Protection (OLP)

Whenever  $V_{SENSE}$  voltage falls below  $0.5V$ , or equivalently  $V_{OUT}$  falls below 20% of its rated value, it indicates an open loop condition (i.e.  $V_{SENSE}$  pin not connected) or an insufficient input voltage  $V_{IN}$  for normal operation. It is implemented using comparator  $C2a$  with a threshold of  $0.5V$  as shown in the IC block diagram in Figure 6.

### 3.8.4 First Over-Voltage Protection (OVP)

Whenever  $V_{OUT}$  exceeds the rated value by 8%, the over-voltage protection OVP1 is active as shown in Figure 6. This is implemented by sensing the voltage at

$V_{SENSE}$  pin with respect to a reference voltage of  $2.7V$ . A  $V_{SENSE}$  voltage higher than  $2.7V$  will immediately turn off the gate, thereby preventing damage to bus capacitor. After bulk voltage falls below the rated value, gate drive resumes switching again.

## 3.9 Output Gate Driver

The output gate driver is a fast totem pole gate drive. It has an in-built cross conduction currents protection and a Zener diode  $Z1$  (see Figure 14) to protect the external transistor switch against undesirable over voltages. The maximum voltage at pin 8 (GATE) is typically clamped at  $15V$ .

The output is active HIGH and at  $V_{CC}$  voltages below the under voltage lockout threshold  $V_{CCUVLO}$ , the gate drive is internally pull low to maintain the off state.

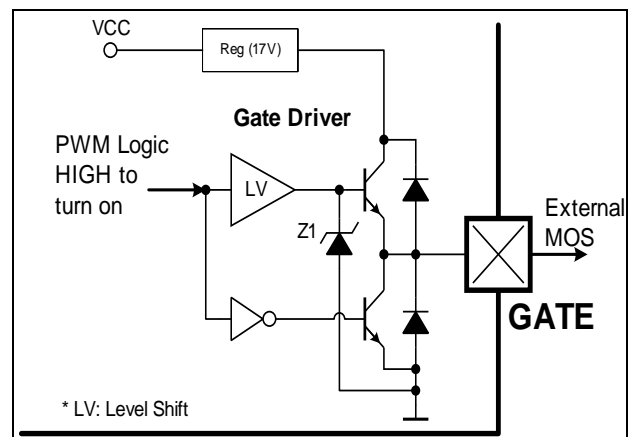

Figure 14 Gate Driver

Functional Description

3.10 Protection Function

Description of Fault	Fault-Type	Min. Duration of Effect	Consequence
Voltage at Pin ISENSE < -400mV	PCL	200 ns	Gate Driver is turned off immediately during current switching cycle
Voltage at Pin BOP < 1V	BOP	20 $\mu$ s	Gate Driver is turned off. Soft-restart after BOP voltage > 1.25V
Voltage at Pin VSENSE < 0.5V	OLP	1 $\mu$ s	Power down. Soft-restart after VSENSE voltage > 0.5V
Voltage at Pin VSENSE > 108% of rated level	OVP1	12 $\mu$ s	Gate Driver is turned off until VSENSE voltage < 2.5V.

## 4 Electrical Characteristics

All voltages are measured with respect to ground (pin 2). The voltage levels are valid if other ratings are not violated.

### 4.1 Absolute Maximum Ratings

Absolute maximum ratings are defined as ratings, which when being exceeded may lead to destruction of the integrated circuit. For the same reason make sure, that any capacitor that will be connected to pin 7 (VCC) is discharged before assembling the application circuit.

Parameter	Symbol	Values			Unit	Note / Test Condition
		Min.	Typ.	Max.		
VCC Supply Voltage	$V_{VCC}$	-0.3		26	V	
GATE Voltage	$V_{GATE}$	-0.3		17	V	Clamped at 15V if driven internally.

**Electrical Characteristics**
**4.2 Operating Range**

Note: Within the operating range the IC operates as described in the functional description.

Parameter	Symbol	Values			Unit	Note / Test Condition
		Min.	Typ.	Max.		
VCC Supply Voltage @ 25°C	$V_{VCC}$	$V_{VCC,OFF}$		25	V	$T_J=25^\circ\text{C}$
Junction Temperature	$T_J$	-25		125	°C	
PFC switching frequency	$F_{PFC}$	21		250	kHz	

**4.3 Characteristics**

Note: The electrical Characteristics involve the spread of values given within the specified supply voltage and junction temperature range  $T_J$  from  $-25^\circ\text{C}$  to  $125^\circ\text{C}$ . Typical values represent the median values, which are related to  $25^\circ\text{C}$ . If not otherwise stated, a supply voltage of  $V_{VCC} = 18\text{V}$ , a typical switching frequency of  $f_{freq} = 65\text{kHz}$  are assumed and the IC operates in active mode. Furthermore, all voltages are referring to GND if not otherwise mentioned.

**4.3.1 Supply Section**

Parameter	Symbol	Limit Values			Unit	Note/Test Condition
		Min.	Typ.	Max.		
VCC Turn-On Threshold	$V_{CCon}$	11.5	12	12.9	V	
VCC Turn-Off Threshold/ Under Voltage Lock Out	$V_{CCUVLO}$	10.5	11.0	11.9	V	
VCC Turn-On/Off Hysteresis	$V_{CChy}$	0.7	1	1.45	V	
Start Up Current Before $V_{CCon}$	$I_{CCstart1}$	-	380	680	$\mu\text{A}$	$V_{CCon}-1.2\text{V}$

		-	0.4	-	V	$I_{GATE} = 0 A$
		-	-	1.4	V	$I_{GATE} = 20 mA$
		-0.2	0.8	-	V	$I_{GATE} = -20 mA$
GATE High Voltage	$V_{GATEH}$	-	15	-	V	$V_{CC} = 25V$ $C_L = 1nF$
		-	12.4	-	V	$V_{CC} = 15V$ $C_L = 1nF$
		8.0	-	-	V	$V_{CC} = V_{VCCoff} + 0.2V$ $C_L = 1nF$

**4.3.10 Gate Drive Section**

Parameter	Symbol	Values			Unit	Note / Test Condition
		Min.	Typ.	Max.		
GATE Rise Time	$t_r$	-	30	-	ns	$V_{Gate} = 20\% - 80\%$ $V_{GATEH} C_L = 1nF$
GATE Fall Time	$t_f$	-	25	-	ns	$V_{Gate} = 80\% - 20\%$ $V_{GATEH} C_L = 1nF$

## 5 Outline Dimension

### PG-DSO-8 Outline Dimension

<sup>1)</sup> Does not include plastic or metal protrusion of 0.15 max. per side

#### Notes:

1. You can find all of our packages, sorts of packing and others in our Infineon Internet Page "Products": <http://www.infineon.com/products>.
2. Dimensions in mm.

# Total Quality Management

Qualität hat für uns eine umfassende Bedeutung. Wir wollen allen Ihren Ansprüchen in der bestmöglichen Weise gerecht werden. Es geht uns also nicht nur um die Produktqualität – unsere Anstrengungen gelten gleichermaßen der Lieferqualität und Logistik, dem Service und Support sowie allen sonstigen Beratungs- und Betreuungsleistungen.

Dazu gehört eine bestimmte Geisteshaltung unserer Mitarbeiter. Total Quality im Denken und Handeln gegenüber Kollegen, Lieferanten und Ihnen, unserem Kunden. Unsere Leitlinie ist jede Aufgabe mit „Null Fehlern“ zu lösen – in offener Sichtweise auch über den eigenen Arbeitsplatz hinaus – und uns ständig zu verbessern.

Unternehmensweit orientieren wir uns dabei auch an „top“ (Time Optimized Processes), um Ihnen durch größere Schnelligkeit den entscheidenden Wettbewerbsvorsprung zu verschaffen.

Geben Sie uns die Chance, hohe Leistung durch umfassende Qualität zu beweisen.

Wir werden Sie überzeugen.

Quality takes on an all-encompassing significance at Semiconductor Group. For us it means living up to each and every one of your demands in the best possible way. So we are not only concerned with product quality. We direct our efforts equally at quality of supply and logistics, service and support, as well as all the other ways in which we advise and attend to you.

Part of this is the very special attitude of our staff. Total Quality in thought and deed, towards co-workers, suppliers and you, our customer. Our guideline is “do everything with zero defects”, in an open manner that is demonstrated beyond your immediate workplace, and to constantly improve.

Throughout the corporation we also think in terms of Time Optimized Processes (top), greater speed on our part to give you that decisive competitive edge.

Give us the chance to prove the best of performance through the best of quality – you will be convinced.
